

Why Did JavaScript Add This “Sugar Layer”?

JavaScript introduced the `class` keyword in ES6 (2015) for two simple reasons:

1 Readability

Manually writing the same prototype assignment over and over across a large software project gets incredibly messy and hard to read.

```
repeated, manually, twenty times: Something.prototype.methodName =  
function() {}
```

2 Familiarity

It made it significantly easier for engineers transitioning from classical languages like Python, Java, or C++ to write clean code without getting tripped up by JavaScript's unique prototypal architecture.

In short: `class` doesn't change how JavaScript works under the hood — it's syntactic sugar over the same prototype-based inheritance that's always been there.
